

# Contribution to the macroinvertebrate fauna of the Hungarian Danube. I. Introduction, sampling sites and methods

JÁNOS N. NOSEK

## Introduction

In the past two decades the biodiversity of the Danube has significantly changed. These changes affected all of the river biota, among them the populations and communities of the profundal and littoral regions (WACHS 1997). Primarily, the species number and the density of the populations decreased, but in certain sections an increase in number of species could also happen. For example in 1967 128 gastropods occurred in the whole length of the Danube (DUDICH 1967), by 1990 this number decreased to 91 (FRANK *et al.* 1990). In 1995 on the Austrian section 1142 benthic species were recorded by MOOG *et al.* (1995), one hundred species less than before (WACHS 1997). The greatest decrease could be detected in the case of litho-rheophile species (Ephemeroptera, Simuliidae, Gammaridae) (TITTIZER *et al.* 1990).

Besides the species number decrease, to a lesser degree, but the appearance and dispersion of new species not registered earlier also play an important role in the changes of biodiversity of a given area. The changes of habitats facilitate the invasion of new species. In the case of the Danube the opening and operation of Rhine-Main-Danube Canal has allowed the direct connection between the two main watershed areas, which step was followed by an enormous increase in ship traffic. In consequence of this direct connection, both the passive dispersion (e.g. larval drift, ship ballast water, bio-fouling) and the active migration of the species promoted the increase of the distribution area of some species and/or the appearance of species in new or modified biotopes emerging by human impacts (TITTIZER 1997a). Since 1992, the opening of the Rhine-Main-Danube Canal, many Pontocaspian species have occurred in the river Rhine (e.g. *Dikerogammarus haemobaphes*, *Dikerogammarus villosus*, *Jaera sarsi*), but other examples confirm the opposite dispersion down stream the Danube (e.g. *Atyaephyra desmaraesti*, *Corbicula fluminea/fluminalis*) (TITTIZER 1997b).

Our knowledge about the macroinvertebrate fauna of the main channel and the side branch systems along the Hungarian Danube section is very diverse in relation to space, time and taxonomic groups. From the period prior to the 60s we have only sporadic data, e.g. about the occurrence of *Limnomyasis benedeni* (Woynarowich 1954). In the first half of the 60s an extensive survey of the macroinvertebrate fauna living in the profundal and littoral regions and in the periphyton of swimming pontoons had been conducted both in the main channel of the river and in the Mosoni Danube (ANDRÁSSY 1962, 1966, BERČZIK 1966a, 1966b, 1969a, 1969b, BOTHÁR 1966, RICHNOVSZKY 1967, SOÓS 1967). DUDICH (1967) had compiled the comprehensive zoological inventory of the Hungarian Danube section on the basis of the formerly accessible literature. From the consecutive periods to the 90s there were only sporadic data (POMICHAL 1984; FRANK

*et al.* 1990, NOSEK & OERTEL 1980/81, PUKY 1994, 1995a, 1996, RICHNOVSZKY 1975). Data from the Soroksár-Danube had been presented by TYAHUN (1977). From the beginning of the 90s macrozoobenthos surveys have started in the frame of biological monitoring of the Hungarian rivers and one part of the data refers to the Danube, too (CSÁNYI 1994, 1996, 1998). Regarding the side branch system of the Szigetköz, there are fewer published data (BERCZIK 1967, NOSEK 1996, PUKY 1995b). Our knowledge is even less about the macroinvertebrate communities of the wetland of the Gemenc area (CSÁNYI *et al.* 1994, RICHNOVSZKY 1963).

Water bugs living in the water and water surface were omitted from hydrobiological surveys during the last decades. To the end of the 90s some data of the saucer bug (*Aphelocheirus aestivalis*) arose from Danube habitats (AMBRUS *et al.* 1995) and the occurrence of *Sigara fossarum* from the Szigetköz was reported (BAKONYI 1990). The aquatic beetle fauna of the Danube was practically unknown, only a few published data existed (ÁDÁM 1992).

From the end of the 90s the number of publications has significantly increased. A part of these publications contain data not only from the water system of the Hungarian Danube (VARGA *et al.* 1997; CSÁNYI 1998–99; KOVÁCS *et al.* 1998–99; VARGA *et al.* 1998–99; CSABAI *et al.* 2001; CSABAI 2002; JUHÁSZ & BÉKÉSI 2002; JUHÁSZ *et al.* 2001, 2002; KOVÁCS *et al.* 2003; KOVÁCS *et al.* 2004; KOVÁCS 2005; KOVÁCS *et al.* 2005), but a great number of publications were really devoted to the Danube or its wetland areas (ANDRIKOVICS *et al.* 2001; UHERKOVICH & NÓDRÁDI 2001, 2003, 2004; NÓGRÁDI & UHERKOVICH 2002; WEINZIERL *et al.* 2002; KOVÁCS & AMBRUS 2003; CSABAI *et al.* 2005; BÓDIS & OERTEL 2005; OERTEL *et al.* 2005; PUKY *et al.* 2005; VÁSÁRHELYI *et al.* 2005; ANDRIKOVICS *et al.* 2006a, 2006b; CSABAI & NOSEK 2006a, 2006b; BÓDIS *et al.* 2006; BÓDIS & NOSEK 2006; PUKY & SCHÁD 2006; BORZA 2007; VÁSÁRHELYI *et al.* 2007).

The publication series starting now will contain the faunistic results of different macroinvertebrate investigations (OERTEL & NOSEK 2006) carried out by the Hungarian Danube Research Station of the Hungarian Academy of Sciences in the last fourteen years. Collections were made by the members of the Station (Erika Bód /BE/, Péter Borza /BP/, Gábor Csörgits (CsG/, Tibor Erős /ET/, János Nosek /NJ/, Nándor Oertel /ON/, Miklós Puky /PM/). In the period 2002–2005 within the frame of a biodiversity survey of the Danube as well as the Szigetköz, Gemenc and Béda-Karapancsa Landscape Protection Areas members of several other institutions joined to the collection (Sándor Andrikovics /AS/ Eszterházy Károly College Dept. of Zoology, Gábor Bakonyi /BG/ Szent István University Dept. Zoology and Ecology, Zoltán Csabai /CsZ/ University of Pécs, Dept. of General and Applied Ecology, Edit Molnár /ME/ Institute of Ecology and Botany of HAS, Tamás Vásárhelyi /VT/ Hungarian Natural History Museum).

## Materials and methods

### General characteristics of the sampling areas

Till the 90s of the last century the 417-km-long Hungarian Danube reach (1850–1434 river km) could be divided into two parts on hydrological basis. The first one from the west border to Gönyű (1850–1794 river km) could be characterised by a higher slope (0,4–0,14 ‰) and current velocity (2,1–1,8 msec<sup>-1</sup>). At Szap (1812 rkm) the slope decreases quick to 0,10–0,08–‰ resulting an enormous bed-load deposition building up the alluvial fan in the Szigetköz and Csallóköz area. The second part reaching from Gönyű to the south border (1794–1434 river km) – apart from the narrow valley of the Danube Bend – is of middle course character with a low slope (0,1–0,04‰) and current velocity (1,2–0,8 msec<sup>-1</sup> in the period of mean water level) (TÖRY 1952).

From 1992 the hydrological conditions of the main channel in the west border-Medve section (1850–1806 river km) have changed significantly due to the diversion of the River Danube to the operation canal of the Bős/Gabcikovo hydroelectric power plant. In the abandoned main channel (Old Danube, 1850 – 1812 river km) the former water discharge ( $2200 \text{ m}^3 \text{ sec}^{-1}$  on average) decreased to  $400 \text{ m}^3 \text{ sec}^{-1}$  (on average). The water level was lowered by 3-4 m, and hence the ground water level was lowered to a great extent, too.

The 57-km-long Ráckevei-(Soroksári-)Danube is the longest side-branch of the Hungarian Danube. It is situated south from Budapest between river kilometres 1842.5 and 1586 on the left side of the main channel. Water regime of the branch is governed by two lock-gates (Kvassay lock-gate on the north and Tassi lock-gate on the south end). The fluctuation of the water level does not exceed 10-20 cm, stream velocity is very low ( $0 - \text{cm sec}^{-1}$ ). The whole side-branch is a recreation area.

Szigetköz, one of the two wetlands along the Hungarian Danube, is situated in the northwest part of Hungary between the main channel of the Danube (border to Slovakia) and the Mosoni Danube down streams from Rajka to the city of Győr. The area of the Szigetköz is 375 km<sup>2</sup>.

Before the 90s of the last century the hydrological regime of the water bodies was governed by the Danube. The separate side-branch systems – in different degree and for various periods of time – were directly connected to the main channel, subject to both the Danube actual water level and the bottom level of the branch. The oxbow lakes on the active alluvial flood plain and on the flood-protected area generally got their water supply by ground water. They were directly connected with the main channel only during high flood periods.

In 1992, after the diversion of the Danube radical alterations occurred in the situation described above. Due to the decrease in water discharge most of the side branches lost their direct connection with the main channel as the water level of the Old Danube became lower than the bottom levels of the upper mouth of the side branches. Both the water level and the area of the oxbow lakes supplied by ground water decreased to great extent.

From 1993 several technical measures have been implemented in order to reduce the scarcity of water. Former independent side branch systems, oxbow lakes were interconnected by new artificial canals and shortcuts or by dredged old natural branches to form a water supply system. To provide the supply system with water by natural gravity, a bottom sill was built in the abandoned main channel at river kilometre 1843, at Dunakiliti in 1995.

The Gemenc Landscape Protection Area, so called „Gemenc”, the last near natural floodplain of the Hungarian Danube is situated on the right side of the Danube between the mouth of River Sió (river km mark 1498) and the mouth of the Báta branch (river km mark 1465).

The area has been formed both by the water regime of the Danube and the human regulating activity. The recent situation is the result of the dam building between 1870 and 1872. The dam followed the estate boundary of the Primateship of Kalocsa between Bogyiszló and Báta, 3–8 km far from the Danube. Due to the river bed allocations of the Danube and the regulating activity there are on the floodplain a lot of side branches, oxbow lakes and wet meadows of different shape and size interconnected with a network of narrow artificial canals, called “fok”. The water level and hence the area, the hydrological character (running or standing water), the duration of inundation and the connection among the different water bodies depend on the actual water regime of the Danube.

Apart from the side branches with permanent flow (e.g. Rezéti-Duna) the water bodies are independent from each other unless the water level of the Danube exceeds 350 cm on the water level gauge at Baja. Connection of the water bodies begins through the canals (“fok”) depending on their bottom level between 400 and 450 cm. Above 450 cm streaming will be permanent and at water levels greater than 600 cm the majority of the floodplain is covered by water.

Surface waters of the Béda-Karapancsa Landscape Protection Area are situated on both sides of the Danube. They are partly backwaters of former Danube side branches ( e.g. Külső-Béda, Belső-Béda, Bédai-holtág, Boki-Duna, Riha-tó, Baracska-Duna, Kadia), partly artificial canals connecting the backwaters (Ferenc-csatorna, Karapancsa-főcsatorna, Déli-fögyűjtő, etc.). Apart from a few exceptions (Külső-Béda, Mocskos-Duna) they lie on the protected area.

#### *Sampling sites*

Collections were made in a total at 451 sampling places within the above mentioned areas. Table 1 contains the list of sampling sites, their codes, geographical positions, locality (administrative unit), the codes of microhabitats from where animals were collected and the water system or landscape to which the site belongs. As in the subsequent papers presenting the results of separate taxonomic groups the sampling sites will be referred to by codes, so Table 1 contains the sites listed in alphabetical order of their code to make the search easy.

**Table 1.** Characteristics of sampling sites. (Explanation: aaf = active alluvial floodplain, ág = branch, ágréndzsér = branch system, árvágás = cutoff,

bulkó = weir, csatorna = canal, föcsatorna = main canal, holtáig = oxbow lake, láp = marsh,

LPA = Landscape Protection Area, mellékág = side branch, morotva = oxbow lake, tó = lake, sziget = isle, zátony = bank.

Explanation of abbreviations in column “microhabitat” see in Table 2).

### Sampling methods

According to the various taxonomic groups, developmental stages, water bodies and substrates different collection techniques were used. Sampling was made in the littoral zone of the different water bodies. Light traps were placed near the riverside (GOD1, 10 m from the Danube) and on the roof of the building of Hungarian Danube Research Station (GOD0, 150 m from the Danube). Artificial substrates were placed 20–25 m from the shoreline (according to the actual water level) immediately under the water surface (Mf) and near the bottom (Ma).

EU ISO-7828-1985 hand net (0.4 x 0.4 m) was used in two ways:  
in running waters up to 1 m depth in the case of coarse bed material (cobbles, pebbles, sand) it was used with the kicking and sweeping technique (**H**),  
above different bed material and along rip-rap zones without kicking the substrates (**V**).

On the riverside in shallow water Surber-sampler (**S**) (0.25 x 0.25 m) and core samplers (**T**) (0.04 and 0.19 m in diameter) were applied.

For collecting from soft bed material (mud, silt, fine organic deposit) triangular dredge (0.25 m) (**D**), Ekman-Birge-grab (**G**) (0.16 x 0.16 m), Petersen-grab (**P**) (0.31 x 0.31 m) and core samplers (**T4** 0.04 m, **T19** 0.19 m diameter) were used.

Macroinvertebrates from the macrophyte stands were collected by handnets (**K**) of different shapes. From submerged vegetation in deeper water circular net (0.25 m), from littoral and submerged vegetation in shallow waters semicircular net (0.25 m) and from dens emergent vegetation (reed, rushes *Phragmites*, *Typha*, *Acorus*, *Juncus* etc.) a drop-shaped net (KERTÉSZ et al. 1985) was applied. From stones, submerged trunks, tree branches animals were collected by hand (**C**) using forceps. Periphyton growing on different substrates was scraped (**L**) into a semicircular handnet.

In 1999 at two sites (GOD0 and GOD1) light traps (**Fc**) were also operated to collect Ephemeroptera, Odonata, Trichoptera, Heteroptera and Coleoptera (ANDRIKOVICS et al. 2001).

In 1999 and 2000 during 30-week-long periods artificial substrates (**M**) were used in a colonization study of macroinvertebrates. Results of faunistic interest will also be published in the series.

In some cases bottle traps (**Pc**) were also used, and some data originate from gut content analyses (**I**).

All net samplers were fitted with nets of 720 µm of mesh size. Opening width of the samplers is in parenthesis.

The different sampling methods according their codes are listed in Table 4.

**Table 4.** Codes for different sampling devices and methods applied

<b>C</b>	sampling by hand
<b>D</b>	triangle dredge
<b>E</b>	electric fishing
<b>F</b>	freeze corer sampling
<b>Fc</b>	light trap
<b>G</b>	Ekman-Birge grab
<b>H</b>	handnet with kicking and sweeping technique
<b>I</b>	gut content analysis
<b>K</b>	handnet among aquatic macrovegetation
<b>L</b>	scraping
<b>Ma</b>	artificial substrate above the bottom
<b>Mf</b>	artificial substrate at the water surface
<b>P</b>	Petersen grab
<b>Pc</b>	bottle trap
<b>S</b>	Surber sampler
<b>T19</b>	core sampler of 19 cm diameter
<b>T4</b>	core sampler of 4 cm diameter
<b>V</b>	handnet without kicking technique

In the subsequent papers the code of the sampling site will be followed by the code(s) of the sampling method(s) used. If subsamples were collected at the same sampling site using different methods and these subsamples were mixed in situ, the codes of the separate methods follow closely each other. For example: GOD1-HDC means that at sampling site GOD1 subsamples were taken by hand net with kicking and sweeping technique, by triangle dredge and by hand and these subsamples were put together.

Sampling usually was made at day, but in some cases it was made at night. These cases are denoted by letter N in parenthesis after the code of the sampling method (CSA5-H(N) means kicking and sweeping sampling at night at sampling site CSA5).

Samples were fixed in situ by formaldehyde solution of 4%. The conserved material was separated into taxonomic groups and preserved in ethyl alcohol of 70%.

**Acknowledgement:** Investigations were supported by the Hungarian Scientific Research Fund (OTKA) Grant No. T025419, T037468, T046180, by the Ministry of Environment and Water and its legal predecessors. Thanks are due to Mrs Irma Kelényi-Welner for the laboratory work.
